## Bits & Pieces

### ON GOTO ELSE

A useful sequence in BASIC is IF - THEN - ELSE. Unfortunately, as everyone knows, PET BASIC can't do an IF THEN ELSE, or can it? Well, the answer is no, it can't. However, a lot of times the 'THEN' keyword is followed by a line number which really means GOTO. IF GOTO ELSE we can do!

The common approach in BASIC is an IF statement followed by some 'if criteria', followed by THEN or GOTO and a line number. Anything beyond here will be ignored since if the condition is satisfied, the GOTO is executed, and if not, BASIC drops down to the next line of the program. Therefore, the next line usually contains the 'ELSE' code. For example:

```
100 IF X=B GOTO 120 : X=X+1 : GOTO 100
```

...will never work. Even though it does absolutely nothing, to do it correctly we need:

```
100 IF X=B GOTO 120  
110 X=X+1 : GOTO 100
```

To get it all on one line we use the ON GOTO statement:

```
100 ON -(X=B) GOTO 120 : X=X+1 : GOTO 100
```

True/false logic in PET BASIC produces a "0" for false and "-1" for true (try PRINT 4=5, 5=5). A negative argument will give ?ILLEGAL QUANTITY ERROR so we change the sign with -(A=B). Fortunately, an argument that is out of range (ie.'0') for ON GOTO will not cause execution to drop to the next line but rather continue with the next statement. This is also true if there are not enough line numbers following the GOTO to satisfy the argument. For example:

```
100 ON PEEK(32768+X) GOTO 120 : X=X+1 :GOTO 100
```

...will GOTO 120 only if the character PEEKed is an "A".

Commodore, The Microcomputer Magazine

When you think about it, an IF THEN ELSE is only useful if you can fit the IF criteria, the THEN criteria and the ELSE criteria all on one line, which is often not possible. Using this variation of ON GOTO, you'll get the IF and ELSE criteria on one line; the THEN conditions will go elsewhere. Additionally, you can have several THEN conditions just by adding more line numbers.

### MisguideINT

In algebra, the integer of a decimal number is defined as the next lower whole number past the fractional part. Therefore:

```
PRINT INT (1.3)
1
PRINT INT (-1.3)
-2
```

One might expect the second example to return "-1". But BASIC is doing it right. If you want the next lower whole in order of magnitude, you'll have to code:

```
PRINT INT (ABS (-1.3)) * SGN(-1.3)
```

Of course "-1.3" will probably be a variable in your program. One last note... integer variables automatically do an INT operation on decimal numbers:

```
A% = INT (A)   is the same as
A% = A
```

### PET/CBM EPROMs

EPROMs come in all shapes and sizes but not all work with PET/CBMs. The most useful ones are the 4K and 2K sizes. There is also a 1K EPROM which you could probably get quite cheap, but this is getting somewhat small and wasteful of valuable address space.

The part numbers are set up so that the last 2 digits represent the number of K bits, so this number divided by 8 gives K bytes. Here is a list of EPROMs that DO work with PET/CBMs:

```
2532 - 4K byte
2716 - 2K byte
2516 - same chip as above
2708 - 1K byte
2508 - same chip as above
```

Several manufacturers (Texas Instruments, Motorola, Hitachi, etc.) produce these chips so you might find some letters before or after the part number. The 2516s and 2716s are virtually the same IC (ie pin for pin compatible), but the 2732s and 2532s are quite different. The 2732 won't operate in the PET due to power supply requirements. The T.I. TMS2716 is also incompatible.

Any local electronics shop should have availability information and EPROM programmers with software are available through some Commodore dealers or see the ads in Compute!, BYTE, etc.

### Invade Invaders

Paul Higginbottom has a quick note for 'Invaders' players (from Midnight Software Gazette):

- \$0E01 (3585) - sets speed you move & fire; normally 2
- \$0E09 (3593) - sets invader firing speed; normally 4
- \$0E0E (3598) - sets mother ship speed; normally 6

Finally, \$0623 (1571) contains the character after missiles to erase them. Try POKEing with 102 (\$66) for Wall Invaders.

### 80/40 Vision

Jim Butterfield doesn't have bionic eyes but he does have a way to test for 80 or 40 column screen:

```
WD=80 : POKE 32768+1024, 96 : IF PEEK(32767)=96 THEN WD=40
```

# BackPack

## Standard Features:

- Full power to PET/CBM for a minimum of 15 minutes
- Installs within PET/CBM cabinet
- No wiring changes necessary
- Batteries recharged from PET/CBM integral power supply

## Specifications:

- Physical Size: 5.5" x 3.6" x 2.4"
- Weight: 4.5 lbs.
- Time to reach full charge: 16 hours
- Duration of outputs: Minimum of 15 min.
- Voltages: +16, +9, -12, -9
- Battery Life Expectancy: 3 to 5 years
- Battery On-Off Switch

## For Use With:

- Commodore PET/CBM 2001 and 4000 series computer
- Commodore PET/CBM 8000 series computer (screen size will not be normal on battery back-up)
- Commodore C2N Cassette Drive

# BATTERY BACKUP SYSTEM

## FOR COMMODORE PET/CBM COMPUTERS

Never again lose valuable data because of power shortages or line surges. **BackPack** supplies a minimum of 15 minutes reserve power to 32K of memory, the video screen and tape drive. **BackPack** fits inside the PET/CBM cabinet and can be installed easily by even the novice user. **BackPack** is recharged during normal operation and has an integral on-off switch.

**BackPack** comes fully assembled and tested. Instructions included.

# Floppy **BackPack**

## Standard Features:

- Full power to Commodore Dual Drive Floppy Disk for a minimum of 15 minutes
- Installs within Disk Drive cabinet
- No wiring changes necessary
- Batteries recharged from Disk Drive's internal power supply

## Specifications:

- Physical Size: 5.5" x 3.6" x 2.4"
- Weight: 4.5 lbs.
- Time to Reach Full Charge: 16 hours
- Duration of Outputs: Minimum of 15 min.
- Voltages: +16, +8
- Battery Life Expectancy: 3 to 5 years
- Battery On-Off Switch

## For Use With:

- Commodore CBM 2040 Dual Disk Drive
- Commodore CBM 4040 Dual Disk Drive
- Commodore CBM 8050 Dual Disk Drive

# BATTERY BACKUP SYSTEM

## FOR COMMODORE DUAL DRIVE FLOPPY DISK

Floppy BackPack is a total, rechargeable, battery backup system for the Commodore line of Dual Drive Floppy Disks. Used in conjunction with BackPack (battery backup for the PET/CBM) it is now possible to save valuable data to either disk drive during power shortages and line surges. Floppy BackPack also reduces chances of disk damage in the 2040.

Floppy BackPack fits inside the disk cabinet and can be installed easily by even the novice user. Floppy BackPack is recharged during normal operation from the disk's own internal power supply and has its own integral on-off switch.

Floppy BackPack comes fully assembled and tested. Instructions included.

BASIC Plotter

Paul Higginbottom  
Commodore Canada

This program will plot random lines using the "quarter-square" graphics characters. Although it's a program in itself, it could easily be made into a subroutine.

The program has been set up for 80 column screens (line 9040). Notice "LL" (Line Length) is multiplied by 2 in lines 2020 & 2030? Since the quarter squares use up half a character space in the "x" direction, an 80 column screen can have up to 160 "half-characters" horizontally. Similarly, on 25 lines there can be up to 50 half characters vertically ("y" direction). For 40 column screens you'll need to change LL to 40; the second parameter remains the same since both have 25 lines.

Line 2000 clears the window (if one set), the screen, and sets graphics mode (no gap between lines). If you like, substitute CHR\$(142) with 'esc-rvs-N' and stick it inside the quotes.

```

2000 PRINT"[HM HM CLR]"CHR$(142)
2010 GOSUB 9000
2020 X1=INT(RND(TI)*LL*2) : Y1=INT(RND(TI)*50)
2030 X2=INT(RND(TI)*LL*2) : Y2=INT(RND(TI)*50)
2040 GOSUB 3000 : Y1=Y2 : X1=X2 : GOTO 2030
3000 REM ***** PLOT A LINE *****
3010 DX=X2-X1 : DY=Y2-Y1 : X=X1 : Y=Y1
3020 L=SQR(DX*DX+DY*DY) : IF L=0 THEN 3040
3030 XI=DX/L : YI=DY/L
3040 GOSUB 8000 : IF (ABS(X2-X)<=ABS(XI)) AND
      (ABS(Y2-Y)<=ABS(YI)) THEN RETURN
3050 X=X+XI : Y=Y+YI : GOTO 3040
8000 REM ***** PLOT X, Y *****
8010 TX=INT(X+IR):TY=INT(Y+IR) :SQ=AM(TX AND AM, TY AND AM)
8020 P=BS+TX/DV-INT(TY/DV)*LL : POKE P, C(I(PEEK(P))OR SQ)
      : RETURN
9000 REM ***** SETUP *****
9010 DIM C(15), I(255), AM(1,1)
9020 FOR I=0 TO 15 : READ C(I) : I(C(I))=I : NEXT
9030 FOR I=0TO1 : FOR J=0TO1 : AM(J,I)=(J+1)*4+I : NEXTJ,I
9040 LL=80 : BS=32768+24*LL : DV=2 : AM=1 : IR=.5
9050 DATA 32, 123, 108, 98, 126, 97, 127, 252,
      124, 255, 225, 254, 226, 236, 251, 160
9060 RETURN

```

The subroutine at 9000 sets up an array with the 16 possible combinations of the quarter squares. BS is the base address or the POKE address of the bottom left corner of the screen.

All plotting efforts are performed by the two subroutines at 3000 & 8000. Subroutine 3000 plots a line from x1,y1 to x2,y2 by plotting several points (sub 8000). At the same time, subroutine 8000 must determine if there is already a point in a character space. If there is, the POKE information must not interfere with existing points.

Lines 200X are used for plot criteria generation. The above merely plots random lines. For something more meaningful, try substituting with these:

```

2020 X1=0 : Y1=1
2025 FOR X2=0 TO 159
2030 Y2=EXP (X2/31.4)
2040 GOSUB 3000 : Y1=Y2 : X1=X2 : NEXT : END
  
```

```

2020 N=6 : C=3.1415926/160 : X1=0 : Y1=25
2025 FOR X2=0 TO 159
2030 Y2=25 + 24 * SIN(X2 * N * C)
2040 GOSUB 3000 : Y1=Y2 : X1=X2 : NEXT : END
  
```

```

2020 N=8 : C=3.1415926/160 : X1=0 : Y1=50 : DC=100
2025 FOR X2=0 TO 159
2030 Y2=25 + 24 * COS(X2 * N * C) * EXP(-X/DC)
2040 GOSUB 3000 : Y1=Y2 : X1=X2 : NEXT : END
  
```

The first plots an exponential curve. Notice the Y origin is set to 1 rather than 0. This accounts for a slight inaccuracy as the plotter draws horizontal lines using the top "half-character" rather than the bottom half-character. This could be changed by modifying the character table at 9050.

The second draws a SINE curve starting half way up the screen (Y1=25). The variable N represents the number of half cycles displayed (N=6 will draw 3 complete cycles).

The last one is a decaying COSINE wave, origin at top-left (Y1=50). For higher decay rates, use lower values in DC.

Finally, with little effort you could use the plotter routine to draw axes for your functions.

'Now, You Say the Last Time  
 You Saw It Was in a Macro  
 You Were Coding...'

## The Machine Language Monitor - An Introduction

When the first 2001 Series PET hit the market back in 1978, the first programs Commodore released were Squiggle, Bigtime and The Machine Language Monitor. Back then, the M.L.M. was loaded from tape. Commodore decided to introduce the M.L.M. to the next version of BASIC. The two became great companions and have been rommies ever since! (ugh. So much for PET folklore!)

The Machine Language Monitor is quite simply a utility program for performing more direct operations on machine memory and processor registers. For example, the BASIC SAVE command is used to store the contents of BASIC text space. The M.L.M. 'S' command can be used to save ANY part of memory because the start and end addresses are given by the user, not pre-determined by the machine.

In this article, I'll attempt to give a brief overview of the main sections of the M.L.M, plus some explanation of the 6502 microprocessor registers. For more details on machine language, there are several good books on the subject. Three are: MOS 6502 Programming Manual (see your dealer), 6502 Assembly Language Programming by Lance A. Leventhal (any good computer store), and the PET Machine Language Guide by Arnie Lee (Abacus Software).

### Engaging the M.L.M.

There are two ways to enter the M.L.M. program. They are known as "break to the monitor" and "call to the monitor". In 6502 machine language, a BRK (break) instruction is represented by hex 00. Therefore, a SYS to any location in memory that contains a zero, will result in a "break to the monitor":

```
SYS 1024 ;brackets around  
SYS 4    address unnecessary
```

The contents of decimal locations 1024 and 4 are always zero (unless deliberately altered). For example:

```
SYS4  
  
B*  
    PC  IRQ  SR  AC  XR  YR  SP  
.; 0005 E455 30 00 5E 04 F8  
.
```

Notice the 'B\*' at the left margin. This indicates break to the monitor. To "call" the monitor, one must SYS to the location in ROM at which the monitor program starts:

```
SYS 64785 :BASIC 2.0  
SYS 54386 :BASIC 4.0
```

A 'C\*' will be displayed for call to the monitor.

## M.L.M. Commands

There are 6 M.L.M. commands:

- R - display Registers
- M - display Memory
- G - Go or execute memory
- X - Exit to BASIC
- L - Load
- S - Save

Several monitor extension programs have been released that offer extra commands in addition to the above six. Programs like NEWMON, SUPERMON and EXTRAMON are loaded into RAM and link themselves in with the M.L.M. in ROM to produce a more sophisticated monitor utility. However, for now we'll concentrate on the resident commands.

### R - Display Registers

When the M.L.M. is entered (SYS 4, etc.), the registers are automatically displayed. These registers are, from left to right, the:

Program Counter	(PC)
Interrupt Request vector	(IRQ)
Status Register	(SR)
Accumulator	(AC)
X Register	(XR)
Y Register	(YR)
Stack Pointer	(SP)

All of these registers, except IRQ, are contained inside the microprocessor. They have NO equivalent PEEK address and are only accessible through machine language. However, the M.L.M. allows screen editing here so you can change the values of the registers with the cursor.

#### The Program Counter (PC)

The PC register always shows the address of the next instruction that will be executed. Notice that if you enter with SYS4, the PC will show 0005.

#### The IRQ Vector

Every 60th of a second the PET performs an interrupt. During the interrupt, the PET flashes the cursor, updates the clock, checks the stop key and scans the keyboard. Once again, all this is done by a machine code routine resident in ROM. The IRQ vector designates the starting address of this routine. You can change the IRQ vector (using the cursor), but the change does not take place until a 'G' command is given. Also, exit to BASIC ('X') resets the IRQ vector back to the original contents.

## The Status Register (SR)

The Status Register (sometimes called the 'P' register) is used to indicate the status of the microprocessor. Each bit of this register is used to represent some condition in the processor as a result of the events leading up to its' interrogation.

- Bit 0 - C - Carry Flag
- 1 - Z - Zero Flag
- 2 - I - Interrupt Disable
- 3 - D - Decimal Mode
- 4 - B - Break Command
- 5 - - Not used
- 6 - V - Overflow Flag
- 7 - N - Sign Bit

## The Accumulator (AC)

The Accumulator is your main work register in the microprocessor. One can bring data into the accumulator and transfer it elsewhere in memory or perform operations on it such as AND, OR, ADC, etc.

## The X and Y Registers (XR & YR)

These registers are auxillary registers. Although they can be used for data transfers, they are more often used as index registers for the accumulator.

## The Stack and the Stack Pointer

The stack is an area in RAM used by the microprocessor to store registers temporarily while another task is performed that requires the use of those same registers. The stack is located from \$0100 to 01FF. That's 255 bytes of the total 1K that PET takes away from you on power up. This area is critical for proper machine operation and no POKES should be made here. The stack is often used to store return addresses for subroutines AND interrupts. All registers are also pushed on the stack before servicing an interrupt and pulled off the stack back into their respective registers at the end of an interrupt. Several arithmetic routines also use the stack extensively.

The Stack Pointer is used as an index pointer into the stack area. As the 6502 throws stuff onto the stack, it must keep track of which byte it can use next. The SP starts at \$FF and decrements each time data is pushed on the stack. This means that the first byte onto the stack would occupy location \$01FF. The SP would decrement by 1 and the next byte on would go into \$01FE, and so on. As these bytes are removed from the stack, SP is first incremented, and the processor gets the byte contained in location \$0100 + SP, or more formally, \$0100,SP. Afterwards the Stack Pointer is conveniently left pointing at the next available location. (For more info on the stack, see Transactor #1, Vol3, pg5)

## M - Display Memory

The 'M' command can be used to display any part of memory in the entire 64K range. Like the registers, this is also in hexadecimal. Syntax for the command is 'M,[start address],[end address]'. For example:

```
          PC  IRQ  SR AC XR YR SP
.; 0005 E455 30 00 5E 04 F8
.M,0400,0401
.: 0400 00 00 00 AA AA AA AA AA
```

The M.L.M displays groups of eight bytes on a line. Unless your end address is an even multiple of 8, you will always be shown the remainder of the line. Screen editing is allowed here too. Simply move the cursor over to the byte. Changes occur when RETURN is hit. The address can also be altered to duplicate lines into other memory addresses (like duplicating a line of BASIC by changing the line number and hitting RETURN).

## G - GO or Execute

This command is equivalent to a GOTO as opposed to GOSUB. Programs should end with a BRK (hex 00) rather than an RTS. Upon executing the BRK, the registers will be displayed and you're back in the monitor.

The 'G' command can be used two ways. Once a machine language program is entered, a 'G' command followed by a hex address will start executing memory at the address specified.

If no address is given, execution will begin at the address shown by the Program Counter (PC). On a BRK, the PC will be left pointing at the address following the BRK instruction. After examining the registers, another 'G' command with no address would perform the equivalent of a CONT (continue).

## X - Exit to BASIC

Quite simply, the 'X' command does a warm start to "READY." and you're back in BASIC.

## L - Load

Unlike the BASIC LOAD command (or DLOAD), a monitor Load brings in files without changing any of the pointers that support BASIC text. This can be useful when you have a BASIC program already loaded and you would like to bring in a machine language utility.

BASIC programs can also be loaded with 'L', but pointers would not be set correctly and proper operation would be hampered. For example, NEW the machine and use the M.L.M. to load a BASIC program. You can LIST the program, but RUNNING

the program will produce unpredictable results. LIST the program again and you'll notice your BASIC text has been clobbered. This is because the Start of Variables Pointer was not set properly to the end of BASIC but rather remained set pointing at the beginning of BASIC. As variables get set from within the program, BASIC begins building a variables table according to the address specified by the start of variables pointer. If this pointer is at the start of BASIC, whammo!... the variables table gets built right on top of your BASIC.

Syntax for the command is:

```
'L [filename],[device #]'
```

A drive number preceding the filename is optional and the device # must be in 2 digit hexadecimal. For example:

```
      PC  IRQ  SR AC XR YR SP
.; 0005 E455 30 00 5E 04 F8
.L "1:some program",08
searching for some program
loading
.
```

#### S - Save

Probably the most important of the M.L.M. commands. The 'S' function can be used to store any part of memory from zero page, cassette buffers, BASIC text, the screen, right up through BASIC ROM and the operating system. This command is most appreciated when a crash occurs that clobbers the BASIC operating system. Such situations are usually caused by a faulty machine code subroutine that you might be testing. When the BASIC SAVE command returns ?SYNTAX ERROR, it's nice to know that you can salvage the program from the M.L.M. Syntax is:

```
'S [drive#]:[filename],[device#],[start addr],[end addr+1]'
```

Due to a small bug, add 1 to the end address chosen. The byte at the resultant end address is not saved.

```
      PC  IRQ  SR AC XR YR SP
.; 0005 E455 30 00 5E 04 F8
.S "1:screen contents",08,8000,9000
.
```

The above would store an image of the screen out to a disk PRG file. Of course the monitor display would be stored too, but this would be impossible with an ordinary BASIC SAVE.

There is one exception when dealing with cassette tape. Due to the tape routines and format, the cassette will not accept addresses above \$7FFF, or more precisely, addresses with bit 15 set to 1. Since the start address is stored in the file header, a save of memory above \$7FFF will not be properly sent to the cassette. However, I can't think of a

single reason why this would be necessary since there's not much you could do with it on tape.

### Summary

With this information in hand, you'll probably find yourself more intrigued by the concept of "machine language" (that is if you're not already). As mentioned earlier, there are several monitor extension programs that add some extremely useful commands to the built-in M.L.M. Commands like disassemble, single step, hunt, transfer, interrogate, and assemble make life a lot easier. A little practice and you'll find that machine language is not as tough as it's made out to be. With many sophisticated assemblers now available, you might even find machine language easier than BASIC!

Features Of  
The 6845 Video Controller

JIM HOLTOM  
Control Microsystems

All Commodore machines that have 12" monitors (8032, fat 4032, 8096, and SuperPET) employ a device known as the 6845 video controller to generate the video signals. Some come with a 6545 but they're both the same.

The chip has 18 programmable registers that are accessed through 2 memory locations at \$E880 and \$E881 (59520 and 59521). To read or write a register, the number of the register (0-17) is stored in 59520 and that register can then be accessed through 59521. This method saves considerably on address space.

The device is used to control such functions as character height, cursor size, horizontal position, vertical resolution, etc. Here is a summary of the registers and their functions:

- R0 - Horizontal Total Register. Horizontal frequency equalling the total of displayed plus non-displayed "character time units" minus 1.
- R1 - Horizontal Displayed Register. Number of displayed characters per horizontal line.
- R2 - Horizontal Sync Position. Controls horizontal positioning.
- R3 - Horizontal Sync Width. 4 bits which control the width of the horizontal sync pulse.
- R4 - Vertical Total. The vertical frequency is controlled by R4 and R5.
- R6 - Vertical Displayed. Number of displayed character rows on the video.
- R7 - Vertical Sync Position. Controls vertical positioning.
- R8 - Interlace Mode. 2 bits which determine whether interlaced or non-interlaced mode is employed.
- R9 - Maximum Scan Line Address. 5 bits determining the number of scan lines per character row including spaces.
- R10 - Cursor Start. 7 bits for cursor start scan line and blink rate.
- R11 - Cursor End. 5 bits for cursor end scan line.
- R12 - Start Address. R12 and R13 control the first address put out as a refresh address after vertical blanking. R12 is the low 8 bits and R13 is the hi 6 bits of the address.
- R14 - Cursor Register. This 14 bit register stores the cursor location. R14 is the 8 low and R15 is the 6 hi bits.
- R16 - Right Pen. 14 bits of R16 and R17 store the contents

All registers are write only with the exception of R14, R15, R16 and R17. This means the registers 0-13 can only be POKEd. PEEKing these registers will return invalid results.

### Interesting Effects

In the early days, it was possible to blank the screen of the 2001 PET. This was useful for visual effects. BASIC 2 machines omitted this capability which was unfortunate. Now it's possible again! The following program demonstrates screen blanking for 12" monitor machines:

```
10 FOR J=1 TO 2000 : PRINT "*"; : NEXT : REM FILL SCRNRN
20 POKE 59520, 1 : REM HORIZ DISPLAY REG
30 POKE 59521, 0 : REM NO WIDTH = NO DISPLAY
40 FOR J=1 TO 2000 : NEXT : REM DELAY
50 POKE 59521, 40 : REM VIDEO BACK ON
```

Notice that the register offset (59520) need not be set again to access the same register as before. Default display width for 40 and 80 columns screens is "40".

The horizontal and vertical positioning of the display area can be altered by POKing different values into R2 and R7. R2 default is 41 and R7 default is 29.

The number of displayable character columns may be modified by POKing different values into R1. R1 default is 40. Likewise, the number of displayable character rows can be changed using R6. R6 default is 25.

The machine makes use of the controller for things like windowing, and text/graphic modes. Several other effects could certainly be achieved for use in games and other applications. The combinations and permutations are virtually endless!

### Editor's Note

A word of caution. Uneducated experimentation with the 6845/6545 can potentially crash the computer. The effects involving the registers that Jim talks about are all safe to play with but other registers should be left alone unless you know what you're doing.

Getting Usable Video  
Signals From 12" Monitor PET/CBMs

Jim Law  
Batteries Included

This program works with any "fat" Commodore computer (8032, 12" 4032, 8096, and SuperPET). It re-configures the video controller to produce signals which more closely approximate the standard video sync signal frequencies. For those wishing to use an external video adapter to display the PET screen on a video monitor, this program can save having to modify the monitor.

The PET screen remains completely readable, with only minor narrowing of the picture and the possibility of loosing part of the bottom line in text mode. However, this can be corrected with a slight adjustment\* to the PET video section.

Video adapters formerly used with 9" screen machines will not work directly with the new 12" machines as the polarity of the video out and horizontal sync signals have been reversed at the User Port. Correct this with:

```
POKE 59520, 12 : POKE 59521, 0
```

This will give the desired effect on the external monitor but the PET screen will be inverted (but still readable). To get back to normal, POKE 59520, 12 : POKE 59521, 16

Some video interfaces for 9" machines have a horizontal sync position control and thus may accept the inverted pulses. People have used this system and it saved them having to obtain new interfaces.

Video adapters for 12" screen machines are now becoming more readily available and may be used with this program to produce an external picture which might otherwise be unable to "sync" to the strange signal frequencies coming from a 12" machine without this program.

A universal video adapter is available from Batteries Included in Toronto (416 596 1405) as well as "Video+"; a ROM which alters the signals at power-up and eliminates the need for this program. Video+ replaces the ROM at UD7 and does not interfere with normal operation.

```
100 DATA 0, 59, 2, 47, 4, 26, 5, 8, 7, 25, 9, 9
110 DATA 0, 59, 2, 47, 4, 33, 5, 6, 7, 30, 9, 7
120 FOR J=1 TO 6 : READ A, B
130 POKE 59520, A
140 POKE 59521, B
150 NEXT J
160 POKE 59468, 14 : PRINT CHR$(14)
170 PRINT "HIT 'STOP' FOR TEXT MODE CONFIGURATION"
180 GET A$: IF A$="" THEN 90
190 FOR J=1 TO 6 : READ A, B
200 POKE 59520, A
210 POKE 59521, B
220 NEXT J
230 POKE 59468, 12 : PRINT CHR$(142)
240 PRINT "HIT 'STOP' FOR GRAPHICS MODE CONFIGURATION"
250 GET A$: IF A$="" THEN 250
260 RESTORE : GOTO 120
```

PRINT-AT RoutineJacques Lebrun  
Lennoxville, Quebec

Ever had to print at random locations on the screen? Most programmers probably have. The only way provided by the BASIC interpreter is to use cursor down, up, left and right enclosed within quotes in print statements. This could be impractical for some programs which constantly print something at different places on the screen.

Here is a cure: a machine language PRINT-AT routine that allows a BASIC program to print anywhere on the screen with a simple SYS command. The routine is location independent which means that it can execute well no matter its location in memory. The best place is probably the first cassette buffer for those who never use cassettes. The routine is for BASIC 4.0 but could be modified for other BASICS

The routine can be used two ways. The first one is to position the cursor only. This allows further PRINTS, INPUTS and GETs to be done at that new location on the screen. Format is:

SYS ADDR,ROW,COL

The second way positions the cursor and prints whatever text follows the SYS. Its format is:

SYS ADDR,ROW,COL,TEXT

'ADDR' is the starting address of the routine, 'ROW' and 'COL' are two numeric expressions. 'ROW' ranges from 0 to 24 and 'COL' ranges from 0 to 79. 'TEXT' can be any numbers of string, integer or floating-point expressions separated by commas or semi-colons just as a normal PRINT statement.

```
100 REM *** BASIC LOADER FOR PRINT-AT ROUTINE ***
110 REM *** SET VARIABLE AD TO DESIRED STARTING ADDRESS ***
120 AD=634
130 FOR I=AD TO AD+41
140 READ A
150 POKE I,A
160 NEXT I
170 END
180 DATA 32, 245, 190, 32, 212, 200, 224, 25
190 DATA 176, 28, 134, 216, 32, 111, 224, 32
200 DATA 245, 190, 32, 212, 200, 224, 80, 176
210 DATA 13, 134, 198, 32, 118, 0, 240, 9
220 DATA 32, 245, 190, 76, 168, 186, 76, 115
230 DATA 195, 96
```

## The Print Mint

Jim Butterfield, Toronto

The usual point of programs is that they produce output. The normal way of producing output is by using the PRINT command or its cousin, PRINT#. We can abbreviate PRINT with a question mark (?), but oddly enough, PRINT# can't be shortened that way: typing ?# will produce a program line that lists as PRINT#, but doesn't work.

### Other Ways.

We can generate output without using PRINT. It's not always good practice, but we can POKE to the screen memory area. This can be good for graphic games and animations, but there are several bonus things we get by using PRINT. First, PRINT keeps track of the line position for us, and starts a new line as necessary. Secondly, PRINT doesn't limit output to the size of the screen: when the screen fills up, scrolling is automatic. Finally, and most important, PRINT can easily be changed to PRINT# to allow output to be directed to other devices such as printer, modem, disk or cassette tape. In contrast, screen POKES are absolutely limited to the size of the screen, and can't be easily redirected anywhere else.

### Punctuation.

If you say 'PRINT X' you will print the value of X and start a new line. The absence of punctuation at the end of the PRINT command signifies, "That's the whole thing; print it and wrap the line up." In contrast, if you say 'PRINT X;' you will print the value of X but you won't go to the next line: the invisible cursor will wait behind the printed value. This sounds a little backwards: you do something extra if you have no punctuation, but you do nothing if you have a semicolon.

There's one other form of "formatting" punctuation: the comma. If you type 'PRINT X,' you will print the value of X and then skip ahead to the next "column". Columns are considered to start at positions 11, 21, 31 and so on up to position 71. They exist only on the screen; saying 'PRINT#4, X,' to send to printer or other device won't set up columns properly. The comma will produce quick and convenient output to the screen, but it may be a bad habit since you can't use it anywhere else.

We can use this punctuation within a Basic PRINT statement as well as at the end. 'PRINT A;B\$;C;' will generate the values of variable A, string B\$, and variable C one behind the other and will leave the cursor positioned behind the value of C.

### Neat Input.

We can use this punctuation to generate prompting for INPUT statements. For example, if we wanted to add ten numbers, we might code:

```
100 PRINT "INPUT EACH NUMBER:"
110 FOR J=1 TO 10
120 PRINT J;
130 INPUT X
140 T=T+X
150 NEXT J
160 PRINT "TOTAL IS";T
```

We prompt for the ten numbers with 1? ... 2? ... 3? ... and so on. The prompting number is printed by line 120 - J is stepping from 1 to 10 - and the question mark from the INPUT statement appears behind it because line 120 ends in a semicolon; after printing the number we wait on the same line so that the question mark will appear there. Question: What would happen if line 120 ended with a comma instead of a semicolon? Try it and see.

### Number Formats.

Numbers are printed in a special format. First, there is either a space for positive numbers or a minus sign for negative numbers. Then the number appears, as many digits as required plus a decimal point if needed and perhaps even "E" notation. (Never heard of E notation? Try PRINT 3E2 and see if you can figure it out). Finally, the number is followed by a cursor-right on the screen.

This seems at first to give you two spaces between numbers, but there are one or two fine points that are useful to know. If you type PRINT 2;3;4 you will see two spaces appear between each set of digits. Now try this: Type a bunch of x characters over the answer (a row of xxxxxxx...) and then cursor back to the PRINT statement and press RETURN again. Some of the x's don't go away; that's because a cursor-right skips over that part of the screen without writing there.

There are a couple of ways to eliminate this difficulty if it bothers you. If you change a value to a string before printing, the cursor-right won't be performed. You could type PRINT STR\$(2);STR\$(3);STR\$(4) - the same numbers will print with at least part of the problem solved. If you happen to have an 80-column or Fat-40 4.0 system, you may type: PRINT CHR\$(16);CHR\$(22);2;3;4 and you'll discover the problem is solved quite elegantly.

Here's another exception to the two-spaces rule: Type PRINT 2;-3;-4;5 and look at the result. The minus signs take up one of the two positions, and now there's only one space between some numbers.

### Summary.

PRINT is handy and versatile. It takes a little while to get used to the formatting of the PRINT statement, but you'll soon have good control over your output.

There are some fascinating things you can PRINT which cause the screen to do unusual things. More about them another time.

Programming TipsPaul Higginbottom  
Commodore Canada

First I would like to answer some frequently raised questions about screen formatting of data, and then take a look at a few techniques to make programs smaller and more elegant.

Number Juggling

Formatting numbers on the screen can cause problems when the TAB function is used. If a numbers are to be printed in columns, then it would be nice to ensure that the decimal point of the numbers always line up in the column.

For example, if the number is simply TABbed onto the screen, and the number is a "0", then it will appear at the left hand side of the column, which doesn't look very smart. It is therefore necessary to use the length of the number (ie. the number of digits including decimal points) to drive the TAB expression. A number has a leading space and a trailing cursor right which needs to be taken into consideration. The LEN function counts the number of characters in a string. In order to use LEN it is first necessary to convert the number into a string using STR\$. The number of characters in the number is given by:

$$X = \text{LEN} ( \text{STR\$} ( A ) ) - 1$$

...where A is the number. The trailing cursor right is ignored by STR\$ but 1 is subtracted to take account of the leading space. So now, taking the above example, if we were to TAB(10-X) we would be in business, right? No, not quite yet.

There are a couple more possibilities that should be considered. Sometimes it is desirable to tack leading zeroes onto integer numbers (ie. to display "0038" rather than "38"). With decimal numbers, we may want a specified number of digits following the decimal place, followed by trailing zeroes which the PET does not do for us. All of this will affect the positioning of numbers output to the screen.

Without question, the easiest way to handle number formatting is to first turn the number into a string:

$$A\$ = \text{MID\$} ( \text{STR\$} ( A ) , 2 )$$

STR\$ converts "A" to a string and the MID\$ function is used to take the 2nd character onwards, thus removing the leading space. To add leading zeroes we use the RIGHT\$ function:

$$A\$ = \text{RIGHT\$} ( "000000" + A\$ , 4 )$$

Assuming "A" is an integer, the above will produce a 4 character string. The number of leading zeroes will be dependent on the size of "A" (ie "16" produces "0016" and "1024" stays "1024"). For compactness, all of the above could have been done with:

$$A\$ = \text{RIGHT\$} ( "000000" + \text{MID\$} ( \text{STR\$}(A) , 2 ) , 4 )$$

Rounding decimal numbers and adding trailing zeroes is a little trickier. First we must decide how many significant digits are to follow the decimal place. The following is an example for 2 significant digit truncating:

```
A = 1035.55534
A = INT (A * 100) / 100
PRINT A
1035.55
```

The above merely moves the number two places to the left, chops off the fractional part, and then moves it back two places to the right. However, this is not rounding but rather truncating, which is not the same. For rounding, we must first decide what degree of rounding is desired. Most often, numbers are rounded to 2 decimal places, or "to the penny". Our example then becomes, simply:

```
A = 1035.55534
A = INT (A * 100 + .5) / 100
PRINT A
1035.56
```

The same result would be accomplished by first adding .005 to A and multiplying that by 100, but BASIC is more accurate at decimal arithmetic that lies closer to the decimal point.

Numbers that end up with 1 decimal or less will need trailing zeroes. Once again, this can be done with a string manipulation. For example:

```
A = 1035.59534
A = INT ( ABS(A) * 100 + .5) / 100)
PRINT A
1035.6
S$ = CHR$ (32 - (V<0) * 13)
A$ = MID$ ( STR$ (INT(A)) ,2)
DP = INT ((A - INT(A)) * 100 + .5)
A$ = A$ + "." + RIGHT$ ("00" + MID$ (STR$(DP) ,2) ,2)
A$ = RIGHT$ (" " + S$ + A$ ,10)
PRINT A$
1035.60
```

This probably looks sort of clumsy but it's designed to do everything; trailing zeroes; pos. and neg. rounding; and decimal point alligning. Notice that we've taken the ABSolute value of A before entering the routine. S\$ will be either a space or a minus sign. Then we grab the INTeger part of A into A\$. DP is used to take the decimal part of A, and round it on the left of the decimal point. Next we build it all together by taking the integer part, adding our own decimal point, followed by the decimal part. As usull, the leading space is stripped off DP with MID\$. "00" is added to this (remember, DP could have a value of say 04 or an even 0) and RIGHT\$ comma 2 gives us our 2 decimal places. Lastly we add some leading spaces (which could also be zeroes) and then we stick the sign S\$ of the front.

Easy, right? Well, you might have done it differently but this was a string juggling exercise for the practice. For a formatting routine that's even more cryptic than this one, see Jim Butterfield's PRINT USING in Transactor #1, Volume 3.

### Variable Flip-Flop

Programs can be shortened a great deal with a little thought and an active imagination. For example, it is often necessary to set a flag if a condition is met or to compliment the flag. One might code:

```
1200 IF FLAG=0 THEN FLAG=1 : GOTO 1220
1210 FLAG=0
1220 ...
```

On consideration, the statement

```
1200 FLAG = 1 - FLAG
1210 ...
```

will be seen to have the same effect.

### Screen Codes To ASCII

This program is a screen dump routine which makes it possible to copy the contents of the screen onto the printer. This subroutine has been presented several times but we'll be looking at technique as opposed to operation.

```
5000 OPEN 4, 4
5010 FOR J = 0 TO 999
5020 P = PEEK (32768 + J)
5030 GOSUB 5500
5040 IF P< 64 THEN P=P+ 64 : GOTO 5090
5050 IF P<126 THEN P=P+128 : GOTO 5090
5060 IF P<128 THEN P=P+ 64 : GOTO 5090
5070 IF P<191 THEN P=P- 64 : GOTO 5090
5080 IF P=255 THEN P = 191 : GOTO 5090
5090 PRINT #4, CHR$ (P);
5100 X=X+1 : IF X=40 THEN PRINT#4 : X=0 : F=0
5110 NEXT
5120 CLOSE 4
5130 RETURN
5500 REM REVERSE FLAG
5510 IF F=1 AND P>127 THEN 5550
5520 IF P>127 THEN F=1 : PRINT#4,"[RVS]"; : GOTO 5550
5530 IF F=0 AND P<127 THEN
5540 IF P<127 THEN F=0 : PRINT#4,"[RVS OFF]";:GOTO5550
5550 RETURN
```

As you can see, the routine begins PEEKing the screen into P. The subroutine at 5500 deals with reverse field characters. Then P is converted to its corresponding CHR\$ value and it's sent to the printer. Lines 5010 and 5100 are set up for 40 columns but this can easily be changed to 80.

Now let's have a closer look at those five nasty IF statements. If we look at the differences between PEEK/POKE codes and ASCII, it becomes apparent that only the 3 most significant bits (bits 5 [32], 6 [64], and 7 [128]) are changed. "Aha, a bit of boolean algebra will solve this problem!" Using the OR and AND functions, it is possible to make the conversion with just one line! Thus if P=PEEK(32768), the top left corner of the screen, then:

$$C = (P \text{ AND } 127) \text{ OR } ((P \text{ AND } 64) * 2) \text{ OR } ((64 - P \text{ AND } 32) * 2)$$

where C is the corresponding ASCII character. Here's the new program:

```
5000 OPEN 4, 4 : T=40 : S=32768
5010 FOR J = S TO 33767 : P=PEEK(J)
5020 R$ = CHR$(146-(PAND128))
5030 R$=LEFT$(R$,-(P>127ANDPEEK(J-1-(J=S))<128ORP<128AND
    PEEK(J-1-(J=S))>127))
5040 P=(P AND 127)OR((P AND 64)*2)OR((64-P AND 32)*2)
    -((PAND127)=0)*64
5050 PRINT#4, R$;CHR$(P);
5060 IF (J-32807)/T = INT((J-32807)/T) THEN PRINT#4
5070 NEXT : CLOSE4
```

The extra little bit at the end of 5040 takes care of "@" signs that have a screen code of zero. Lines 5020 and 5030 generate a RVS ON or RVS OFF character and then decide whether to send it or not (5030). This is dependent on the field of the last character. The routine has one bug though; if quotes are printed to the printer, any RVS or RVS OFF characters sent will appear literally. If you expect there may be quotes, you'll need to modify so that a CHR\$(141); is sent to do a carriage return with no line feed. Then you'll need to position back to where you left off.

This routine is dreadfully slow but it was meant to be an exercise in boolean algebra. Several screen print utilities have been released that are in machine code. (KEYPRINT, Compute! and TPUG Club Library)

### Abacus

My final program has no application apart from fun. It is a pseudo abacus or bead counter.

```

*-----*
**-----*
***-----*
****-----*
*****-----*
*****-----*
*****-----*
*****-----*
*****-----*
*****-----*

```

```
100 POKE 59468, 14 : PRINT "[CLR] ABACUS" : C=12 : D=9
110 E=102 : L=64 : B=81 : R=13 : X=14 : S=1
120 FOR I=1 TO 9 : PRINT CHR$(230);
130 FOR J=1 TO I : PRINT CHR$(209); : NEXT
140 FOR J=I TO 22 : PRINT CHR$(192); : NEXT
150 PRINT CHR$(230) : NEXT I
160 FOR I=1 TO 9 : P(I)=33179-I*40 : NEXT ;FOR 40 COL
160 FOR I=1 TO 9 : P(I)=33579-I*80 : NEXT ;FOR 80 COL
170 C=S : REM SETS ROW TO 1
180 P=P(C) : REM SET SCAN LINE POSITION
190 IF PEEK(P)=L THEN P=P-S : GOTO 190
200 IF PEEK(P)=E THEN 230
210 POKE P, L : P=P+S : POKE P, B : IF PEEK(P+S)=L
    THEN 210
220 GOTO 170
230 T=D-C : FOR I=S TO X+C-S : POKE P(C)+R-I, L :
    POKE P(C)+Q-I-T, B : NEXT : C=C+S : GOTO 180
```

Using variables instead of constants (100-110) gives a faster execution time:

E = Edge POKE code for CHR\$(230)  
the shade character  
B = Bead code  
S = Starting row (1 being bottom)  
L = Line POKE code (abacus bars)

Lines 120-150 draw the initial display. The next job is to create an array with the poke addresses of the mid points of each row. The array must match the position of the initial display. If you want to move it, you'll also have to modify line 160.

Lines 170 onward do the rest. The routine uses a scanning technique that scans from the middle of the bottom row moving left (190) until it finds something that is not a line. If it is a bead then line 210 pushes that bead along the bar until that bead hits something that is not the bar (either the right hand edge or another bead). If it finds the left hand edge before finding a bead (200) then it knows that all of the beads have been moved over to the right. Now it moves them all back and pushes one over to the right on the next row up (240, 180 & 190).

One thing I found is that the beads move very fast. If you want to slow them down, add a delay loop in 190:

```
190 IF PEEK(P)=L THEN P=P-S : FOR I=1 TO 20 : NEXT :
    GOTO 190
```

I will leave you with a final puzzle - how long will it take before the top bead moves?

VIC-20 Cartridge DevelopmentPaul Higginbottom  
Commodore CanadaPower-Up Activity

When the VIC-20 is powered on, it looks for a sequence of bytes in a place in memory, which will tell the computer whether or not there is a cartridge plugged in. If this pattern of bytes is not present, the VIC goes about its usual chores, and comes up with the familiar message:

\*\*\*\* CBM BASIC V2 \*\*\*\*

3583 BYTES FREE (may be a different amount)

READY.

The Sequence of Bytes

The sequence of bytes the VIC-20 is looking for are located from \$A004 to \$A008. They should contain:

Hex Address	Hex Contents	CBM ASCII Equivalent
\$A004	\$41	"a"
\$A005	\$30	"0"
\$A006	\$C3	"C"
\$A007	\$C2	"B"
\$A008	\$CD	"M"

To recap then, "a0CBM" is the sequence. If the VIC does see this sequence, what does it do? Well, that's what the first four bytes from \$A000 to \$A003 are for. If the VIC sees the sequence, it will hump indirectly through \$A000, ie. using the vector at \$A000 as a power up address. In laymans terms, this means wherever your code is that you want to execute at power-up, the address of it should be stored in "low, high" format at \$A000 and \$A001. This will be known as the "cartridge cold start vector".

That still leaves \$A002 and \$A003. They form another vector called the "cartridge warm start vector". This will be vectored through whenever an "NMI" interrupt occurs. For those that are not aware of this, the RESTORE key actually generates an NMI interrupt, and so it may be used to re-start a game, or better still if pressed while holding down another key simultaneously (usually RUN/STOP) to avoid accidental re-starts.

An example in assembly coding might be:

```

*= $A000
;
.WORD COLD ;LOW, HIGH VECTOR TO FIRST INSTRUCTION
.WORD WARM ;LOW, HIGH VECTOR ON "WARM START"
;
.BYT $41, $30, $C2, $C3, $CD
;
;IGNORE NMI INTERRUPTS
;
WARM PLA
      TAX
      PLA
      TAY
      PLA
      RTI
;
COLD  <- CARTRIDGE CODE STARTS HERE.
;

```

### BASIC Programs in a Cartridge

It is inadvisable to try to "RUN" BASIC programs out of a cartridge. A compromise would be to do the usual power-up activities (ie. test RAM, etc.) and then "move" the BASIC program from the cartridge to RAM, and execute (probably easiest to do by putting a RUN<RETURN> in the keyboard buffer). It is also inadvisable to put BASIC in a cartridge anyway because of the hazard of someone putting the code onto a more "transportable" medium such as tape or disk. This can be partially avoided by disabling the RUN/STOP key, and the RESTORE key by using the WARM start vector, and changing the IRQ vector into the cartridge.

### Cartridge Standards

Here are some standards that have been laid out for operation of cartridge software:

1. Users should have the opportunity to adjust the screen before commencing; horizontal adjust (\$9000) using the cursor left/right key and vertical adjust (\$9001) using cursor up/down.
2. Where applicable, games should have both keyboard and joystick/paddle control. The keys to use are:

```

                                Up
                                P
A - "fire"                    Left - L ; - Right
                                .
                                Down

```

3. Also where applicable, F1 and F3 are used to choose 1 or 2 players. Afterwards, F1 is used to start play action. Provide about a 5 second delay between "Play Player 1" and "Play Player 2".
4. Function key 7 should flip interlace mode. Some TVs scan every raster "one after another". Other TVs scan every second raster, then go back and do the "in between" rasters. The VIC chip can provide for this by simply setting or unsetting bit 7 of \$9000. The user will decide which looks best.
5. Finally, the combination of the RUN/STOP and RESTORE keys should re-boot the game, as if power were interrupted.

LEARN

### Discover how easy it is for you to get useful results from your VIC.

Understanding Your VIC Volume 1: Basic programming uses a proven step-by-step approach to teach programming. It costs \$11.95

A cassette tape with two demonstration programs from the book is available for \$7.95. It will save you typing time and eliminate typing errors.

A Little VIC Music.

Jim Butterfield, Toronto

The following program plays music on the VIC. It's the simple round, Frere Jacques. The music is listenable, and the program is worth looking at, too.

You'll note that the three voices of VIC are different. Voice three is sharper, and is better for carrying the tune. Voice one is the softest.

Hope you don't mind my breaking up the listing with comments.

```
90 REMARK: FRERE JACQUES /JIM BUTTERFIELD /DECEMBER 81
    This tells you who to blame.
100 DIM A(8)
    Makes room for eight voices. How come? We only have
    three voices on the VIC and four "lines" in the song.
    Watch for the trick.
110 POKE 36878,8
    Set volume (for maximum use ;15)
120 FOR A=5 TO 0 STEP -1
    Here's our main loop. We're going to play the tune six
    times.
130 T=TI+S
140 IF TI<T GOTO 140
    This waits for time "S" before allowing the program to
    continue. The time is measured in "jiffies": units of
    1/60 second.
150 READ S, A(A+0), A(A+1), A(A+2), A(A+3)
    Here comes the song data. It's taken from the DATA
    statements near the end of this program. We're reading
    the data into the table cleverly; this way, each voice
    "comes in" at the proper time.
160 POKE 36874,A(3) : POKE 36875,A(4) : POKE 36876,A(5)
    Play the music! This puts the notes into the VICs
    playing electronics.
170 IF S<>0 GOTO 130
    If there's no more music to play, variable S will become
    zero (from the DATA statement at line 1120) We may want
    to do it again, though.
180 RESTORE : NEXT A
    RESTORE takes us back to the start of the data
    statements (line 1000) so that we can play it again if
    we wish. NEXT A takes us back for the six repeats.
190 POKE 36878,0 : END
    Turn down the volume and quit. The END statement isn't
    really needed here, but it's good practice.
```

The rest of the program is our DATA statements containing the music. It's set up with a timing value followed by the four "parts". By careful reading of the program, you may be able to work out how the different voices come in during the repeats (hint: the key to the trick is in lines 150 and 160).

```
1000 DATA 10, 195, 207, 215, 195
1010 DATA 10, 195, 207, 219, 195
1020 DATA 10, 201, 209, 215, 175
1030 DATA 10, 201, 209, 209, 175
1040 DATA 20, 207, 215, 207, 195
1050 DATA 20, 195, 215, 195, 0
1060 DATA 10, 195, 207, 215, 195
1070 DATA 10, 195, 207, 219, 195
1080 DATA 10, 201, 209, 215, 175
1090 DATA 10, 201, 209, 209, 175
1100 DATA 20, 207, 215, 207, 195
1110 DATA 20, 195, 215, 195, 195
1120 DATA 0, 0, 0, 0, 0
```

It's not very big, but it's interesting to see how the coding comes together. Check Appendix F of your VIC-20 Friendly Computer Guide and you'll see how to set up the notes. Write your own music. If you like programming you might want to try your hand at writing a program which allows DATA statements to be written in easier form. For example, line 1000 might be written as DATA 10,C,E,G,C .. but your program will need to be smart enough to catch the letters and translate them into the appropriate numbers.

Music doesn't have to stand by itself, of course. You could add it as an extra touch to games and animations. Looking at it the other way, you could add to the music - how about a "bouncing ball" program that lets you sing along with VIC?

You can get some nice effects from the VIC, although you'll never quite achieve orchestra quality sound. I can recall showing a group of users some simple music coding on the VIC. At one point, I played a simple rendition of "Dixie", and noticed a listener who had tears in his eyes. I was touched. I asked him, "Are you a Southerner?"

"No," he replied. "I'm a musician."

I guess you can't win 'em all.

Another Voice For The VIC-20

Andy Finkel  
Commodore U.S.A.

Normally, your VIC has 4 musical voices... three music registers and a white noise register. But by connecting a small amplifier to the User Port, and doing a little programming, you can get another musical voice.

The User Port on the VIC is very similar to the PET User Port. This makes it easy to adapt some of the PETs music methods to the VIC-20.

Background - Adding Sound to Older PET/CBMs

Before Commodore introduced the CBM 8032 with a built-in speaker, most PET/CBM users had to develop their own means of getting their computers to squeek, hum, whistle, and sing. They came up with the idea of using the User Port to send square waves through an external amplifier/speaker combination. The shift register could be programmed through BASIC, giving a wide variety squeals, pops, sirens, etc.

Theory

Most music is made up of square waves of different amplitudes and frequencies. One of the functions of the 6522 chip is to generate square waves through the CB2 line. If we connect the CB2 line to a speaker, we will be able to hear the square waves generated by the VIC.

NOTE: Connecting a speaker directly to CB2 may damage your VIC and void your warranty. You must connect the speaker through an amplifier to protect the VIC. See Transactor #6 for a simple amplifier circuit.

BASIC Program Steps

1. Set the 6522 shift register to free running mode by typing:

POKE 37147, 16

2. Set the shift rate by typing:

POKE 37144, C

...where C is an integer from 0 to 255. C is the note to be played.

3. Load the shift register by typing:

POKE 37146, D

...where D = 15, 51 or 85 for a true square wave. This step also sets the octave for the note.

This step must be done last, since as soon as it is set, the VIC starts generating the square waves.

The frequency of the square wave can be found by the following formula:

$$\text{FREQ} = \frac{50000 \text{ Hz}}{(C+2) * (D1)}$$

where D1=8 when D=15  
D1=4 when D=51  
D1=2 when D=85

When you're in this mode, the VIC will not read or write to cassette. To restore normal operation, just type:

POKE 37147, 0

Here are some pre-calculated values for C:

Bb = 251	B = 124
C = 237	C1 = 117
C# = 224	C1# = 111
D = 211	D1 = 104
D# = 199	D1# = 99
E = 188	E1 = 93
F = 177	F1 = 88
F# = 167	F1# = 83
G = 157	G1 = 78
G# = 149	G1# = 73
A = 140	A1 = 69
A# = 132	

The following short program demonstrates music using this method. By hitting a letter, a note will be played.

```

10 PRINT "MUSIC USING CB2"
20 REM A TO G IS ONE OCTAVE, SHIFT A TO G IS ANOTHER
30 PRINT "HIT + TO GO UP AN OCTAVE, - TO GO DOWN"
40 PRINT "[DN] USE ! TO EXIT."
50 POKE 37147, 16
60 DIM A(14)
70 FOR I=1 TO 14
80 READ A(I)
90 NEXT
100 DATA 124, 117, 104, 93, 88, 78, 69
110 DATA 251, 237, 211, 188, 177, 157, 140
200 GET A$: IF A$="" THEN 200
210 IF A$="!" THEN POKE 37147, 0 : END
220 IF A$="+" THEN SF=SF-(SF<2) : GOTO 200
230 IF A$="-" THEN SF=SF+(SF>0) : GOTO 200
240 A=ASC(A$)-64+(ASC(A$)>192)*121
250 IF A>14 OR A<1 THEN 200
260 POKE 37144, A(A)
270 POKE 37146, -(SF=0)*15-(SF=1)*51-(SF=2)*85
280 GOTO 200

```

Joystick Control on The VIC-20

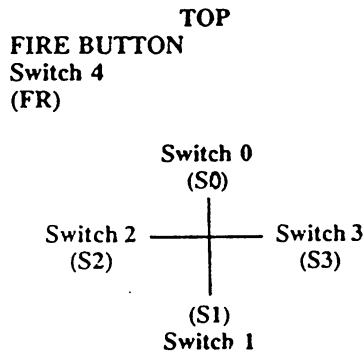

Andy Finkel  
 Commodore U.S.A.

Like all other input and output, the joysticks are controlled using the VIC's 6522 versatile interface adapters (VIAs). The 6522 is a versatile and complex device. Fortunately, it isn't necessary to delve deeply into the mysteries of the 6522 VIA to read the joysticks.

Each 6522 has two Input/Output ports, called port A and port B. Each of the ports has a control register attached called the DATA DIRECTION REGISTER (DDR). This highly important register controls the direction of the port. By using this register, you can use the port for input, output, or both at the same time. To set one bit of the port to output, set the corresponding bit of the Data Direction Register to a 1. To set a bit of the port for input, set the corresponding bit of the DDR to 0. For example, to set bit 7 of port A to input and the rest of the bits to output, POKE a 127 into the DDR for port A.

To read the joystick, one port (and one DDR) of each of the 6522 VIAs on the VIC must be used.

The joystick switches are arranged as follows:

Switch 0, switch 1, switch 2 and the Fire button can be read from VIA #1, which is located beginning at \$9110. Switch 3 must be read from the other 6522 which is located at \$9120.

Now, the key locations for the joystick are as follows:

Hex	Decimal	Purpose
9113	37139	Data Direction Register for I/O Port A on VIA #1
9111	37137	Output Register A Bit 2 - Joy switch 0 Bit 3 - Joy switch 1 Bit 4 - Joy switch 2 Bit 5 - Fire button
9122	37154	Data Direction Register for I/O Port B on VIA #2
9120	37152	Output Register B Bit 7 - Joy switch 3

To read the joystick inputs, you first set the ports to input mode by setting the DDR to 0. This can be done by a POKE. Then the value of the switches can be read with two PEEKs. Sounds easy, right? There is only one problem... VIA #2 is also used for reading the keyboard. Setting the DDR can disrupt the keyscan rather badly. So you have to make sure you restore the DDR to its original condition if you want to use the keyboard afterwards.

To make thing really easy, you can use the following program. Lines 10 to 40 are initialization. The rest of the program, beginning at line 9000, can be called as a subroutine whenever you want to read the joystick.

```

10 DIM JS (2,2) : POKE 37139, 0
15 DD=37154 : PA=37137 : PB=37152
20 FOR I=0 TO 2
25 FOR J=0 TO 2
30 READ JS (J, I)
35 NEXT J, I
40 DATA -23, -22, -21, -1, 0, 1, 21, 22, 23
50 GOSUB 9000
60 PRINT JS (X+1, Y+1)
70 GOTO 50
9000 POKE DD, 127
9010 S3--((PEEK(PB) AND 128)=0)
9020 POKE DD, 255
9030 P=PEEK(PA)
9040 S1--((P AND 8)=0)
9050 S2--((P AND 16)=0)
9060 S0=((P AND 4)=0)
9070 FR--((P AND 32)=0)
9080 X=S2+S3 : Y=S0+S1
9090 RETURN

```

The variables S0, S1, S2 and S3 will be 0 normally, and will be set to 1 (or -1) when the joystick is pointed in that direction. Two of the variables will be set to 1 on diagonal moves. FR will be 1 when the Fire button is pressed, and 0 otherwise.

The AND function is used to pick out one bit of the joystick port. The bits are numbered from 7 (most significant bit) to 0 (least significant bit). By ANDing the 6522 port with a number whose value is a power of two, a single bit is selected (For example, to pick out bit 3, AND with 2, 3 or 8)

The JS array in the program is set up to make it easy to move around the screen using the joystick. The numbers in the DATA statement of line 40 can easily be changed for other purposes. For example, to decode the joystick in this pattern:

```

TOP
0
7 | 1
6 - 8 - 2
5 | 3
4

```

...the DATA statement should be changed to:

Computer Magic

Michael Tomczyk  
Commodore U.S.A.

Writing programs for Commodore's VIC-20 is a lot like performing magic. The results are certainly astounding, and your friends are sure to be amazed!

Actually, computing isn't much different from magic if you're talking about illusions. For example, the VIC automatically tells you if you make a programming mistake by displaying an "error message" on the screen. That doesn't mean there's an "intellectual rabbit" hiding under the keyboard. It simply means the VIC-20 is a "logical" machine.

We're going to explore the VICs peculiar logic - and some magic too. This article will focus on elementary programming to show first-time computer owners how to COMPUTE, with secondary emphasis on hard-line programming. The philosophy is: "You don't have to know how to repair a car in order to drive one; likewise, you don't have to be a computer scientist to "drive" the VIC-20."

That's the beauty of Commodore's "friendly computer." It's easy to learn, fun to "drive", and you don't need a license (or PhD.) to use it.

Everyone likes to perform magic with their new computer, but doing these neat tricks the salesperson showed you in the store doesn't seem so easy when you get the thing home.

Here are some of the favourite programs of Commodore's "VIC Group". These programs are not only fun, but they incorporate some helpful computing techniques which you might want to mix, match, and experiment with. Most of these programs are explained in the VIC owners guide.

Before we begin, here's a quick refresher on how to enter a program into the VIC-20.

1. Type the program line-by-line as shown, including the line number.
2. Hit the RETURN key at the end of each line.
3. Type the word RUN and hit RETURN to make the program execute.
4. To stop a program which is "running", hit the RUN/STOP key.
5. You can RUN a program over and over by STOPping it and typing RUN (because the program stays in the VICs memory when you type it in).
6. Before typing in a new program, type the word NEW and hit RETURN to erase the old program.
7. If a program "hangs up", hold down the RUN/STOP key and hit the RESTORE key. This resets the VIC without losing the program.

### VIC Trick #1: 255 Colours

```
10 FOR X=0 TO 255
20 POKE 36879, X
30 PRINT CHR$(147)
40 FOR T=1 TO 700 : NEXT T
50 NEXT X
```

This little program displays the VICs 255 screen and border colour combinations. It's useful because you can go through all 255 combinations step-by-step, and find the colour combination you like best for a particular program. The POKE command in line 20 is the key. RUN the program until you see a color combination you like. Hit the RUN/STOP key to freeze the colours. Now type PRINT X, and record the value of X for future reference. Type CONT and hit RETURN to continue the program where it left off. This is the lazy approach to choosing colours. The best way is to check page 37 or 134 in the VIC owners guide.

### Vic Trick #2: The Rolling Screen Window

```
10 POKE 36867, 4
20 PRINT CHR$(147)
30 PRINT "YOUR MESSAGE HERE....."
40 FOR X=0 TO 120
50 POKE 36865, X
60 NEXT
70 GOTO 30
```

You can change the screen window of the VIC-20 by using some of the special POKE commands, which change the size and position of the VICs screen window. This little program makes use of these commands to make your message scroll downward across the screen. The message in line 30 should be 22 characters long. Try typing 22 hearts (hold down the SHIFT key and type S) instead of a message.

### Vic Trick #3: The Seasick Program

```
10 PRINT CHR$(147) "SEASICK"
20 FOR L = 0 TO 6.28 STEP .1
30 POKE 36864, 5 + 4 * SIN(L)
40 POKE 36865, 27 + 4 * COS(L)
50 NEXT
60 GOTO 20
```

This program makes the screen move around... and around... and around. We call it the Seasick Program because that's how you might feel if you stare at it too long. The programming magic here is the VICs ability to move the screen horizontally and vertically using POKE statements.

Vic Trick #3: Drawing A High Resolution Circle

```
10 FOR S=7168 TO 7679 : POKE S, 0 : NEXT
20 POKE 36879, 8 : PRINT CHR$(147)
30 FOR S=7680 TO 8185 : POKE S, 160 : NEXT
40 POKE 36869, 255
50 FOR L=0 TO 7 : FOR M=0 TO 7
60 POKE 7680 + M*22 + L, L*8 + M
70 NEXT M, L
80 FOR X=0 TO 63
90 Y1=32 + SQR(64*X-X*X)
100 Y2=32 - SQR(64*X-X*X)
110 FOR Y=Y1 TO Y2 STEP Y2-Y1
120 CH=INT(X/8) * 8 + INT(Y/8)
130 RO=(Y/8 - INT(Y/8))*8
140 BY=7168 + 8*CH + RO
150 BS=7-(X-INT(X/8))*8
160 POKE BY, PEEK(BY) OR (2↑BS)
170 NEXT Y, X
180 GOTO 180 : REM FREEZE PROGRAM
```

This 18 line program looks like a lot... but it does a lot. This is our first program that actually draws something on the VIC-20 screen in high resolution, dot programmable graphics. Dot programmable graphics are different from VIC graphics, in that VIC graphics are made up of 8x8 dot blocks (64 dots per block). Dot programming lets you access each dot individually, and "draw" in high resolution. The mechanics of how to do this are discussed in the VIC-20 Programmers Reference Guide. But, if you really want to get into programmable graphics and plotting, we suggest the VIC-20 Super Expander Cartridge. This special cartridge gives you 3K of extra RAM and adds several new commands to VIC BASIC that let you plot individual points, lines, arcs and circles... and even let you "paint" closed figures on the screen in colour! The Super Expander also has built-in music writing commands and a special "music mode".

We hope this brief "magical" introduction to the VIC gives you some interesting programs to experiment with. If you have a particular topic you'd like us to discuss, please drop a line to:

VIC Loader For PET/CBM

David A. Hook  
Barrie, Ontario

Purpose:

As the VIC-20 becomes more popular, it's likely that users will be exchanging tapes with PET/CBM users. Many people may have a VIC at home, whereas their school or business is equipped with PET/CBM machines.

The VIC has several possible memory configurations, based on what is plugged into the expansion port. The "Start-of-Basic" may be at any of three locations (so far!). To allow for this, the VIC ROMs use a "relocating loader" to place the tape program into memory. Therefore, it merrily accepts BASIC programs saved on either PET/CBMs or other VICs, regardless of the machine used to SAVE it.

Not so for the program saved on the VIC that is subsequently loaded into a PET/CBM! BASIC programs are expected to be found at decimal 1025 (\$0401). Only one of the VIC memory arrangements would have put it there (3K expansion cartridge).

After the LOAD, you may not find anything there when you do a LIST. A couple of tricks have appeared in print to adjust the PET "pointers", but these presumed VIC start-of-Basic at 4097 decimal (\$1001). This only works if it was SAVED with the "as-delivered" 5K unit. (POKE 4096,0:POKE 41,16:CLR was one of these).

If the above two things still didn't work, you could try POKE 4608,0:POKE 41,18:CLR. A LIST command would now probably show the VIC program, and allow you to modify the program.

However, a SAVE to a PET disk would leave you in the same dilemma next time.

Why not a loader program which takes account of these possibilities? It should load the VIC program into the normal PET BASIC area, without the above headaches.

A further incompatibility with the VIC is also overcome:

The VIC operating system allows you to save "program files" which are NOT relocated by the VIC on loading. Machine-language programs and user-defined character sets are two things that SHOULD NOT be parked at a variable address.

A special tape header is written by the VIC when this type is saved. The PET doesn't digest this, so any attempt to LOAD one of these will be ignored by the PET's operating system.

Jim Putterfield's "TINYMON" for VIC uses this "absolute load" feature for any SAVES of memory. My adaptation of his Supermon (for VIC) also copies this technique.

This loader will accept such tapes into the PET, placing them at the same address and reporting start/end locations in hexadecimal.

#### Procedure:

You'll need to do this in three stages:

- 1) Type in the BASIC portion and save it to tape or disk.
- 2) Enter the machine-language monitor, typing a bunch of hexadecimal numbers. Save this part separately, too.
- 3) Combine the two, then SAVE the composite program.

I'll attempt to lead the way through the puzzle... it's not too long a process.

#### Step 1:

If you have Original ROMs (BASIC 1.0), you may retire early. This won't work. For all others, turn your machine off and back on again.

Type in the BASIC portion, by following the printed listing exactly. Don't leave out anything or insert any extra either. Those cursor movement mnemonics should be replaced by their corresponding characters (ie. CLR=Clear Screen, DN=Cursor Down, etc). When you are finished, '?FRE(0)' to check available memory. For 16K this should be 14809 bytes free, and for 32K, 31193 bytes free. Check carefully if you are more than a few different than this.

Do NOT attempt to RUN this yet. (If you cannot resist the urge to check it, put a 'REM' in front of the 'SYS' instruction first).

Save this program to tape or disk, as file name "VL.BAS". Verify it normally. (Did you remember to delete the 'REM' that you inserted?).

#### Step 2:

Consult the "hex dump" of the program, which accompanies this article.

Type 'SYS4' to enter the M.L. monitor. Don't be intimidated by the unfamiliar display... this won't take long.

Beside the ".", type the following:

```
M 0640 06F0      <RETURN>
```

The screen will fill with lots of numbers and letters. Change the values to match the data in the hex dump. Don't forget to hit 'RETURN' at the end of each line. A double-check may save later grief.

When this screen is done, type:

```
M 06F8 07B0      <RETURN>
```

Enter the correct values from the table, and double-check.

Now we are ready to save this part, so type:

```
S "0:VL4.ML",08,0640,07B8  (Drive #0 on disk)
S "VL4.ML",01,0640,07B8   (Tape #1)
```

BASIC 4.0 users can proceed to Step 3. Upgrade (BASIC 2.0) users need to make the following corrections. Type the instructions, then alter the bytes that are displayed to match those below:

```
M 0728 072F
```

```
.: 0728 20 56 F6 20 12 F8 20 0A
```

```
M 0738 073F
```

```
.: 0738 00 20 97 F4 D0 08 4C 6E
```

```
M 075E 076A
```

```
.: 075E 6A E7 A9 2D 20 D2 FF 20
.: 0766 97 E7 20 6A E7 B8 50 28
```

```
M 0797 079B
```

```
.: 0797 B9 F3 4C DD F3 A5 9D 48
```

```
M 07A0 07AF
```

```
.: 07A0 55 F8 A0 00 00 B1 D6 C9
.: 07A8 03 F0 03 4C B0 F5 4C BC
```

Now we are ready to save this part, so type:

```
S "0:VL2.ML",08,0640,07B8  (Drive #0 on disk)
S "VL2.ML",01,0640,07B8   (Tape #1)
```

Step 3:

Get back to BASIC, by typing:

X           <RETURN>

Reload "VL.BAS" followed by the proper "VLn.NL" (n=2 or n=4). Save the composite program with a normal BASIC SAVE command.

Do not make any adjustments to the BASIC portion. It would move the machine language too... and goodbye forever!!!

Barring mistakes, you should be ready to make a go of it now.

Operation:

Type 'RUN' and the program will relocate the machine-language portion. It moves up to high-memory automatically, correcting the necessary pointers. BASIC will not interfere with its operation.

On the screen, the necessary 'SYS' address will be displayed. Copy this down, as it will permit you to disengage the routine with the same 'SYS' call.

The routine is now active. To load a VIC tape into the PET, type:

<V "FILE NAME"       <RETURN>

The "<" must be in the first column of a screen line or the PET will ignore it. The "file name" is optional--if omitted, the load will be done on the first program found.

You will get the normal messages, ie. 'PRESS PLAY...', so follow normal procedure. When the 'READY' message appears and the cursor returns, you can LIST/edit/reSAVE just as if it were entered on the PET in the first place.

If the program was of the special, "absolute load" variety, the PET will load it in the same spot in memory it was SAVED at (on the VIC). However, alongside the file name, the start and end address (in hex) will be printed. This will flag this type of load, and allow you to find it more easily in the PET memory. Both TINYMOM and SUPERMOM for the VIC save memory using this "absolute load" feature of the VIC-20. The PET would ignore the file, without this program.

That's about it. I was able to use this myself on VIXEL#1 (The Code Works) the day after it was finished. It's pretty handy to move VIC programs to PET disk, as a compact back-up medium.

### Editor's Note

If you're wondering why the source code for Daves' Vicloader doesn't match the hex dump, it's because they don't! The BASIC portion of the loader is immediately followed by Jim Butterfields' machine code relocater. After this comes Daves' code which still looks somewhat different from the source output since Jims' relocater demands a specific format. Perhaps JB will document his relocater in a future article so that other ML programmers may include it with new utilities.

## Getting Acquainted With Your VIC20

*Getting Acquainted With Your VIC20* by Tim Hartnell leads the reader, step by simple step, from the absolute basics of programming the VIC to writing complex, sophisticated programs. It thoroughly describes use of the sound, music and color graphics capabilities and illustrates the use of these functions in over 60 programs and games.

By following the comprehensive explanation given for each program and computer function, the reader will learn a great deal about the VIC, the Basic language and micro-computers in general.

Parents and teachers will find the section "VIC as a Teacher" a valuable aid in making the most effective use of the computer in the teaching/learning process.

This book is a worthwhile resource and will help the reader make the most of his computer. The reader will never feel quite the same about it after surviving a round of FRENZY, or listening to the VIC20 compose a 'symphony'.

Softbound, 132 pages, 5 1/2" x 8", \$8.95; add \$1.50 for shipping and handling.

SUPERMON For The VIC

David A. Hook  
Barrie, Ontario

Introduction

No machine language monitor is provided in the VIC ROMs. Serious users find themselves in the same position as the first generation (BASIC 1.0) of PET users. Since only a commercial product, VICMON, is available, the need for a public-domain utility seemed a worthwhile project.

Jim Butterfield has already developed TINYMON1, which may be found in Compute #20 (January 1982). This offers the equivalent to the Commodore TIM monitor.

We've already been accustomed to the benefits inherent in Supermon, Extramon and Micromon for the PET/CBM. Herewith my adaptation of Supermon for the VIC.

While we are on the subject of Jim Butterfield, I once again offer my thanks for his many contributions to the PET/CBM/VIC community. His splendid work and the donation of same to the public domain is quite remarkable. We often fail to acknowledge how rich is our store of knowledge because of this gentleman.

Features

Like its predecessors, VIC-20 SUPERMON loads and self-relocates to the top of VIC memory, regardless of the memory configuration installed. It was designed to fit in less than 2K, and I surrendered the "single-step" mode to accomplish this goal.

Make no mistake, there's a lot of time to be invested to reproduce the code of this program. Since I plan to make this available through the Toronto Pet Users Group, you may obtain this at the April meeting. It should also be part of that evening's "Copy Disk".

The syntax is identical to that of TINYMON1 and Supermon (The Transactor, Vol. II, #11 of November 1980, Compute #19 of December 1981 or The Torpet, Issue #7 of October 1981). See these references for detailed documentation.

I've copied Jim's technique of "absolute-load" files with VIC-20 SUPERMON. This means that if you SAVE memory with the monitor, the VIC won't relocate it on you when you come to re-LOAD the code.

Jim said that the PET would ignore such files, but my utility called VICLOAD covers that shortcoming.

## Procedure

Apart from the investment of time, you don't really need to be familiar with machine-language to enter the program. One of Supermon's benefits is its value for beginners in ML programming.

You'll need a PET/CBM with Upgrade (BASIC 2.0) or BASIC 4.0 ROM installed. Start with a freshly powered-up machine. Enter the ML monitor by typing 'SYS4' and hitting 'RETURN'.

There are 20 screens of information to be entered before you're done. Each requires the same procedure. Only the first (line entry) is slightly different:

1. Immediately after the ".", type the range of memory to be displayed, like so:

```
.M 0028 0028 <RETURN>
```

One line of hexadecimal digits is shown on the screen.

2. Move the cursor back to this line and type over the digits with the values:

```
.: 0028 01 04 DF 0D DF 0D DF 0D <RETURN>
```

Don't forget to hit the 'RETURN' key at the end of each line, or else the new values won't be remembered.

Now type in the starting and ending addresses for each of the 20 screens to be changed. For example, the first would be:

```
.M 0400 0478 <RETURN>
```

Copy the values shown in the accompanying "hex dump" for each block shown. Type right over the existing values, (which will probably show as "AA" on your screen). Do your best to double-check before proceeding with the next block.

Repeat until the block from \$0D80 to \$0DF8 is done. Now exit the monitor, with:

```
.X <RETURN>
```

NOW SAVE AND VERIFY THE PROGRAM. Do not pass "GO", do not collect \$200... do this first!

## Checking

Because of the 2000+ entries you've made, the chance for error is high. Several "Immediate-" or "Calculator- Mode" statements are provided to verify your work.

These statements do a "check-sum" on the total program, each multiple of 5-screens (4 check-sums), and each "line" of 8-entries.

Enter the statements shown, with no line numbers please! On hitting 'RETURN', the total will be shown immediately below.

If your first one shows "283370", then it's probably perfect. Go to the head of the class, and start using VIC-20 SUPERMON.

Otherwise, work your way though the next four, noting which are correct. Each of these totals are a composite of 80 lines of entry, (or 5-screens, as we put them in).

For any incorrect block from above, there is a corresponding statement to type. This will give the individual totals for each line of entry. Mark the lines that are different. You will now have to re-enter the ML monitor and make the necessary corrections. ReSAVE this version and re-do the checksum until it's correct.

## Operation

Disconnect your cassette recorder (power off the PET first, please). Reconnect to the VIC, turn everything on, LOAD VIC-20 SUPERMON and RUN it.

You should be greeted with the so-called "Register Display", as on the PET/CBM. Unless it's a B & W display, you'll see several usages of VIC colour.

Any entries you make will be in blue, while the VIC variously displays red for register headings or errors, purple for normal addresses, black for memory bytes and green for disassembly mnemonics or "next" addresses when assembling code.

Since we are dealing with a 22-character wide screen, the disassembly consumes two lines. The mnemonics are pushed to the right on the second line. More locations would have fit, but I chose to keep the actual "bytes" display. This of course permits you to change them, and causes an automatic redisplay of the same range of addresses.

The goal of "under 2K" was met (by 3 bytes), but the single-step had to be sacrificed. Someone else may re-work Micromon for VIC, but its 4K size is of no use to the "3583 BYTES FREE" crowd.

In Closing...

If I use this half as much as Supermon for PET, it will have been worth the adaptation effort. Without Supermon 1.0 (for Original ROM), this would not have been feasible. A deep bow towards 14 Brooklyn Avenue, Toronto.

### Editor's Note

VICMON is available now from Commodore dealers. Unlike Supermon for the VIC, VICMON comes on a plug-in cartridge. VICMON is a 4K program and doesn't use any of the VICS RAM, leaving more room for your programs. Several additional features include scrolling backwards and forwards, quicktrace, single step, and more! If Daves' Supermon for the VIC wets your appetite for further exploration into the realm of machine language, you'll find VICMON a welcome addition to your programming toolbox!

Your VIC-20 Will Smile...

# VIXEL™

Volume One

**Fire**  
Fly a water-dropping helicopter, and try to put out the high-rise fire before it spreads.

**Draw**  
Be an artist! This high-resolution drawing program makes it easy to create pictures on the screen, and then save them on tape.

**Race**  
Race the computer, head-on! Simple but fun.

The VIXEL #1 cassette costs only \$12.95 in the US and Canada. Foreign orders please add \$3.00 for shipping. CA residents add 6% tax. Visa and MasterCard welcome.

VIXEL is a trademark of The Code Works  
VIC-20 is a trademark of Commodore Business Machines Inc.
