Vol 2
BULLETIN # 7
Dec. 31, 79

This month's Transactor is a collection of all the charts and tables concerning PET and computers in general. Some have appeared in previous Transactors but flipping and finding can be a chore. Therefore a handy reference was thought to be in order.

Also in this Transactor is Bill MacLean's Block Get routine mentioned in Transactor #6 but accidentally omitted

Block Get Routine

Bill MacLean
BMB Compuscience, Canada

The machine language routine below can be used with direct access routines to transfer the contents of a disk buffer into PET memory.

```
100 FOR J = 826 TO 914
110 READ A
120 POKE J , A
130 NEXT
200 DATA 169 ,   0 , 133 ,  52 , 169 , 127
210 DATA 133 ,  53 ,  32 , 248 , 205 ,  32

260 DATA 166 , 210 ,  32 , 198 , 255 ,  32
270 DATA 207 , 255 , 201 ,  10 , 240 , 249
280 DATA 201 ,  13 , 240 ,   8 , 160 ,   0
290 DATA 145 ,   1 , 230 ,   1 , 208 , 237
300 DATA 165 , 210 ,  32 , 204 , 255 ,  32
310 DATA 248 , 205 ,  32 , 159 , 204 , 160
320 DATA   0 , 165 ,   1 , 145 ,  68 , 200
330 DATA 169 ,   0 , 145 ,  68 , 200 , 169
340 DATA 127 , 145 ,  68 ,  96 ,  66
```

Note: For 16K machines, change the three 127's to 63's.

The command to use this program is:

```
SYS 826 , LF# , A$
```

It replaces:

```
INPUT# (LF#), A$
```

It works with ASCII string files only. Any string variable can be used but must be initialized before calling.

```
eg. A$ = "" : SYS 826 , 2 , A$
```

A$ only has to be initialized once.

Since the string is transfered from disk into a dummy input buffer ($7F00 to $8000 on 32K machines, $3F00 to 4000 on 16K), it is necessary to move the record into BASIC string storage. This can be accomplished by:

```
A$ = A$ + ""    or    Y$ = A$ + ""    or    A$(J) = A$ + ""
```

This routine has two advantages over INPUT#. It permits inputting strings up to 255 characters and it strips the Line Feeds placed on disk by PRINT#. Also it is much faster than using GET# in a loop.

Corrections to Transactor #6

In Jim Butterfield's Disk Peek program the print was smudged out in lines 430, 440 and 450. The lines read:

```
430 Y(0)=0:Y(4)=Y(4)+8:J=4
440 IFY(J)>15THENY(J)=Y(J)-16:J=J-1:....
450 PRINT:PRINT"  ";:FORJ=1TO4:....
```

Also, for some strange reason, line 340 may have to be modified for correct operation depending on your machine. Move the second statement of line 340 (GET#1....) to line 345 and change 340 to:

```
340 PRINT#1,"M-R";CHR$(4);CHR$(16);CHR$(1);CHR$(224)
```

Line 235 in Mike Casey's "Tape Index" program should read after the second semi-colon:

```
....INT((L(N,5)-L(N,1))/60);"SEC....
```

The printing mode (standard or lower case) is set by POKEing an address. So as not to disturb any of the other bits in the peripheral control register a safe way to set the lower case mode would be: POKE 59468,PEEK(59468) OR 14 and reset it to standard mode with POKE 59468, PEEK(59468) AND 253 OR 12.

Table: IEEE-488 bus signal.

Bus Group	Signal Abbrev.	Name	Functional Description
Manager	ATN	Attention	The PET (controller) sets this signal low while it is sending commands on the data bus. When ATN is low, only peripheral addresses and control messages are on the data bus. When ATN is high, only preveiously assigned devices can transfer data.
Transfer	DAV	Data Valid	When DAV is low, this signifies that data is valid on data bus.
Manager	EOI	End or Identify	When the last byte of data is being transferred, the talker has the option of setting EOI low. The PET always sets EOI low while the last data byte is being transferred from the PET.
Manager	IFC	Interface Clear	The PET sends its internal reset signal as IFC low (true) to initialize all devices to the idle state. When PET is switched on or reset, IFC goes low for about 100 milliseconds..
Transfer	NDAC	Data Not Accepted	This signal is held low (true) by the listener while reading. When the data byte has been read, the listener sets NDAC high. This signals the talker that data has been accepted.
Transfer	NRFD	Not Ready for Data	When NRFD is low (true), one or more listeners are not ready for the *next* byte of data. When all devices are ready, NRFD goes high.
Manager	SRQ	Service Request	Not implemented in BASIC, but available to the PET user.
Manager	REN	Remote Enable	REN is held low by the bus controller. The PET has a pin grounded that keeps REN permanently low.
Data	DI01-8	Data input/ output lines 1 through 8	These signals represent the bits of information on the data bus. When a DI0 signal is low, it represents 1 and when high Ø.
General	GND	Ground	Ground connections: There are six control and management signal ground returns, one data signal ground return and one chassis shield ground lead.

ADDRESSING MODES

ACCUMULATOR ADDRESSING - This form of addressing is represented with a one byte instruction, implying an operation on the accumulator.

IMMEDIATE ADDRESSING - In immediate addressing, the operand is contained in the second byte of the instruction, with no further memory addressing required.

ABSOLUTE ADDRESSING - In absolute addressing, the second byte of the instruction specifies the eight low order bits of the effective address while the third byte specifies the eight high order bits. Thus, the absolute addressing mode allows access to the entire 65K bytes of addressable memory.

ZERO PAGE ADDRESSING - The zero page instructions allow for shorter code and execution times by only fetching the second byte of the instruction and assuming a zero high address byte. Careful use of the zero page can result in significant increase in code efficiency.

INDEXED ZERO PAGE ADDRESSING - (X, Y indexing) - This form of addressing is used in conjunction with the index register and is referred to as "Zero Page, X" or "Zero Page, Y". The effective address is calculated by adding the second byte to the contents of the index register. Since this is a form of "Zero Page" addressing, the content of the second byte references a location in page zero. Additionally due to the "Zero Page" addressing nature of this mode, no carry is added to the high order 8 bits of memory and crossing of page boundaries does not occur.

INDEXED ABSOLUTE ADDRESSING - (X, Y indexing) - This form of addressing is used in conjunction with X and Y index register and is referred to as "Absolute, X", and "Absolute, Y". The effective address is formed by adding the contents of X or Y to the address contained in the second and third bytes on the instruction. This mode allows the index register to contain the index or count value and the instruction to contain the base address. This type of indexing allows any location referencing and the index to modify multiple fields resulting in reduced coding and execution time.

IMPLIED ADDRESSING - In the implied addressing mode, the address containing the operand is implicitly stated in the operation code of the instruction.

RELATIVE ADDRESSING - Relative addressing is used only with branch instructions and establishes a destination for the conditional branch.

The second byte of the instruction becomes the operand which is an "Offset" added to the contents of the lower eight bits of the program counter when the counter is set at the next instruction. The range of the offset is -128 to +127 bytes from the next instruction.

INDEXED INDIRECT ADDRESSING - In indexed indirect addressing (referred to as (Indirect,X)), the second byte of the instruction is added to the contents of the X index register, discarding the carry. The result of the addition points to a memory location on page zero whose contents is the low order eight bits of the effective address. The next memory location in page zero contains the high order eight bits of the effective address. Both memory locations specifying the high and low order bytes of the effective address must be in page zero.

INDIRECT INDEXED ADDRESSING - In indirect indexed addressing (referred to as (Indirect),Y), the second byte of the instruction points to a memory location in page zero. The contents of this memory location is added to the contents of the Y index register, the result being the low order eight bits of the effective address. The carry from this addition is added to the contents of the next page zero memory location, the result being the high order eight bits of the effective address.

ABSOLUTE INDIRECT - The second byte of the instruction contains the low order eight bits of a memory location. The high order eight bits of that memory location is contained in the third byte of the instruction. The contents of the fully specified memory location is the low order byte of the effective address which is loaded into the sixteen bits of the program counter.
